Explain Distributed Database Architecture

Whichever type of concurrency control a distributed DBMS employs, the messages needed to effect the concurrency control can significantly increase the amount of network traffic among the database sites. Heterogeneous systems are usually used when individual sites use their own hardware and software. A local tables option speeds processing by enabling nodes to define data sets to be managed without cluster-wide replication.

What is Distributed SQL?

You can administer both local and remote databases running on any Oracle platform in any location worldwide.

Distributed Database System

Last but not least, advanced features such as distributed backups and change data capture are not even included in the freemium edition and require a commercial license. Database link management is centralized and simple. It also reduces complexity, contributing to higher reliability and simplified deployment and maintenance.

What is Distributed SQL? An Evolution of the Database

Transaction transparency requires that the DDBMS guarantee that concurrent transactions do not interfere with each other concurrency transparency and that it must also handle database recovery recovery transparency. The Oracle Database server accesses the non-Oracle Database system using Oracle Heterogeneous Services in conjunction with an agent. Each user owns a single schema.

Distributed Database vs. Centralized Database

Homogeneous Database: In a homogeneous database, all different sites store database identically. In a pure that is, not replicated distributed database, the system manages a single copy of all data and supporting database objects.
